Preliminary Bilingual Report: Mixing-Enhanced Interference Games / 双语初步报告：Mixing-Enhanced Interference Games

ECE 752 project progress report generated from the current repository implementation and results/full artifacts. This version is intended to be shareable as a standalone PDF with embedded figures.

中文：本报告基于当前仓库实现与 results/full 中保存的实验结果整理而成，目标是形成一份可以直接发送的、带插图的初步报告。当前最有说服力的证据来自 payoff distortion 与 equilibrium distortion；sanity checks 已完成；dynamics 部分已有数据，但还不足以支持强结论。

English: This report is compiled from the current repository implementation and the saved results/full artifacts. It is intended as a directly shareable preliminary report with embedded figures. The strongest evidence currently comes from payoff distortion and equilibrium distortion. Sanity checks are complete. The dynamics section already has data, but not enough for strong claims.

1. Objective and Current Status / 研究目标与当前状态

中文：项目研究一个 mixing-enhanced interference game，并测试 aggregate、mean-field、sampling 与 no-mixing 等近似是否会破坏 exact game 的战略结构。与只比较单个 payoff 数值不同，本项目更强调 best response、equilibrium 和 dynamics 是否被保留。

English: The project studies a mixing-enhanced interference game and tests whether aggregate, mean-field, sampling, and no-mixing approximations alter the strategic structure of the exact game. Rather than focusing only on individual payoff error, the project emphasizes preservation of best responses, equilibria, and dynamic behavior.

中文：当前仓库已经实现了 exact simulator、approximation baselines、离散均衡枚举、动态仿真和 config-driven 实验脚本。在目标环境 ece752-route2 中，项目测试已通过，因此本报告引用的结果具备基本可复现性。

English: The current repository already implements the exact simulator, approximation baselines, discrete equilibrium enumeration, dynamic simulation, and config-driven experiment scripts. Tests pass in the intended environment ece752-route2, so the results referenced here have a basic level of reproducibility.

2. Sanity Checks / 合理性检查

中文：基础正确性检查已经全部通过，包括 state normalization、cost monotonicity、L=0 与 no-mixing 的一致性、shared target 下的对称性，以及受控 phase perturbation 对 utility 的影响。这些检查说明核心实现没有明显逻辑错误，后续结果具有解释基础。

English: All foundational sanity checks passed, including state normalization, cost monotonicity, consistency between L=0 and no-mixing, symmetry under shared targets, and the effect of a controlled phase perturbation on utility. These checks suggest that the core implementation is logically sound enough to support interpretation of later experiments.

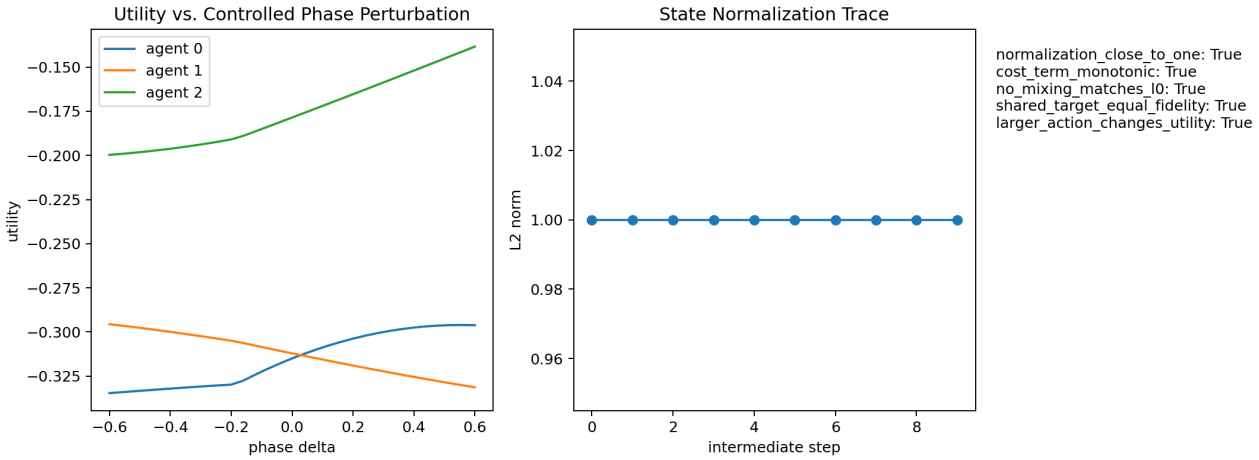

图 / Figure: Sanity checks summary. Summary of normalization and controlled perturbation checks.

3. Payoff Distortion / 收益失真

中文：按 full payoff 实验中的所有 scenario 汇总后，aggregate、mean-field 与 no-mixing baseline 都出现了明显的 utility distortion 与 best-response mismatch。sampling baseline 当前表现很强，但这部分结论需要谨慎，因为其实现仍保留了较多 exact amplitude 信息。

English: Aggregating over all full payoff scenarios, the aggregate, mean-field, and no-mixing baselines all show visible utility distortion and best-response mismatch. The current sampling baseline performs unusually well, but this conclusion should be treated cautiously because its implementation still retains more exact amplitude information than a pure outcome-only approximation.

Baseline	Mean abs. utility error	BR match rate	Rank correlation
aggregate	0.143	0.433	0.577
mean_field	0.074	0.594	0.718
no_mixing	0.118	0.399	0.480
sampling	0.010	0.933	0.982

中文：代表性地看，在 N2_n4_L1_medium_B6 中，aggregate 的平均 utility error 为 0.226，best-response match rate 仅为 0.292。在 N2_n4_L2_high_B10 中，aggregate error 上升到 0.310，而 no-mixing 也达到 0.247。这说明 mixing 与 conflict 的增强会显著削弱压缩近似对战略结构的保真度。

English: As representative examples, in N2_n4_L1_medium_B6 the aggregate baseline reaches a mean utility error of 0.226 and a best-response match rate of only 0.292. In N2_n4_L2_high_B10, the aggregate error rises to 0.310, while no-mixing also reaches 0.247. This indicates that stronger mixing and conflict significantly reduce the strategic faithfulness of compressed approximations.

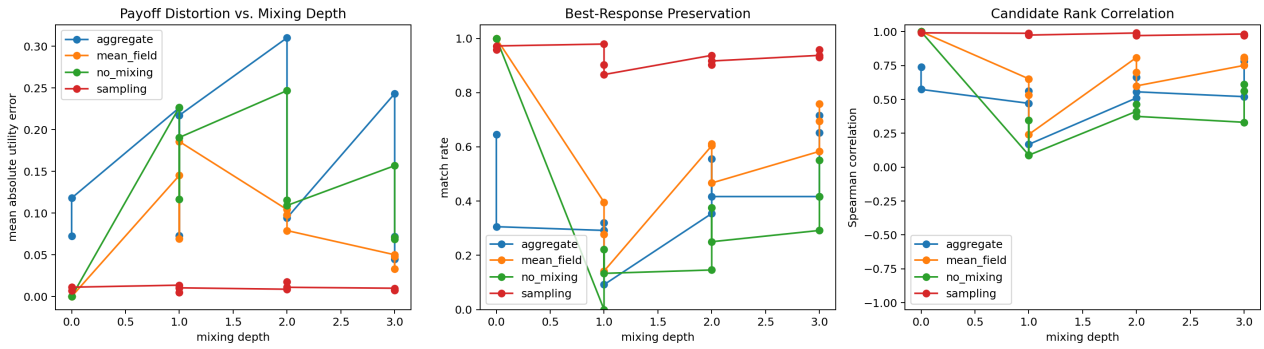

图 / Figure: Payoff distortion, best-response preservation, and candidate rank correlation across mixing depth. Payoff distortion, best-response preservation, and rank correlation across mixing depth.

4. Equilibrium Distortion / 均衡失真

中文：均衡结果比单纯 payoff error 更有说服力，因为它直接说明近似是否会改变游戏的战略结构。在共享目标、无 mixing 的控制组中，aggregate 已经会改变 pure equilibrium 集合；进入 mixing/high-conflict 场景后，多种 baseline 会完全丢失 exact equilibrium overlap，并在重新放回 exact game 时产生较高 regret。

English: The equilibrium results are more compelling than payoff error alone because they directly show whether an approximation changes the strategic structure of the game. Even in the shared-target, no-mixing control case, aggregate already alters the pure equilibrium set. Once the game enters mixing and high-conflict settings, several baselines lose exact equilibrium overlap entirely and incur substantial regret when re-evaluated in the exact game.

Scenario	Baseline	Pure overlap	Exact regret
N2_n2_nomixing_shared	aggregate	0.474	0.013
N2_n4_mixing_high	no_mixing	0.000	0.323
N2_n4_mixing_high	aggregate	0.000	0.304
N2_n4_mixing_high	mean_field	0.000	0.262
N3_n2_mixing_high	aggregate	0.000	0.320
N3_n2_mixing_high	mean_field	0.667	0.033

5. Dynamics and Ablation / 动态行为与消融分析

中文：当前 dynamics 结果最大的特点是保守：记录到的平均 convergence rate 为 0.000，平均 cycle rate 为 0.000。这说明现有配置尚未把 proposal 中设想的 cycling 或 convergence 差异明确激发出来。更合适的表述是，当前已经观察到不同模型在 utility 水平和 trajectory variance 上存在差异，但还不能据此给出关于稳定性机制的强结论。

English: The most important feature of the current dynamics results is their conservatism: the average recorded convergence rate is 0.000, and the average cycle rate is 0.000. This means that the current setup has not yet exposed the cycling or convergence differences anticipated in the proposal. The defensible statement at this stage is that different models already show different utility levels and trajectory variances, but not yet enough evidence for strong claims about stability mechanisms.

中文：消融实验提供了方向性证据。在 A_no_mixing 中，mean-field error 近似为 0.000；引入 mixing 后，在 B_with_mixing 中上升到 0.059。同时，aggregate error 在 D_low_conflict 中约为 0.060，而在 E_high_conflict 中上升到 0.115。这表明 mixing 与目标冲突都可能加剧 approximation failure。

English: The ablation study provides directional evidence. In A_no_mixing, the mean-field error is approximately 0.000; after introducing mixing in B_with_mixing, it increases to 0.059. Meanwhile, the aggregate error is about 0.060 in D_low_conflict and rises to 0.115 in E_high_conflict. This suggests that both mixing and target conflict can worsen approximation failure.

6. Preliminary Conclusion / 初步结论

中文：基于当前结果，本项目已经足以形成一份可信的初步报告。最扎实的结论是：在 mixing-enhanced exact game 中，aggregate、no-mixing 以及部分 mean-field 近似会明显扭曲 payoff ranking、best response 与 equilibrium structure；这种 distortion 在若干 high-conflict 场景下相当显著。需要谨慎的是，sampling

baseline 目前定义得过强，而 dynamics 部分还不足以支撑关于 cycling 或 convergence 的强 claim。

English: Based on the current results, the project already supports a credible preliminary report. The strongest conclusion is that in the mixing-enhanced exact game, aggregate, no-mixing, and in some cases mean-field approximations visibly distort payoff ranking, best responses, and equilibrium structure; this distortion becomes substantial in several high-conflict settings. The main cautions are that the current sampling baseline is defined too strongly, and that the dynamics section still does not support strong claims about cycling or convergence.

中文：因此，当前最合适的外发版本应把 narrative 聚焦在 strategic preservation failure 上，并明确写出两点限制：第一，sampling baseline 需要进一步弱化；第二，dynamics 仍属 ongoing investigation。这样的表述既能展示已有成果，也不会因为结论过度而失去可信度。

English: Therefore, the most appropriate external-facing narrative at this stage is to focus on strategic preservation failure and to state two limitations explicitly: first, the sampling baseline still needs to be weakened; second, the dynamics study remains an ongoing investigation. This framing presents the current accomplishments clearly without overstating the evidence.
